

## CHAPTER 2

# Derivatives

### 2.1 The Derivative of a Function

This chapter begins with the definition of the derivative. Two examples were in Chapter 1. When the distance is  $t^2$ , the velocity is  $2t$ . When  $f(t) = \sin t$  we found  $v(t) = \cos t$ . *The velocity is now called the derivative of  $f(t)$ .* As we move to a more formal definition and new examples, we use new symbols  $f'$  and  $df/dt$  for the derivative.

**2A** At time  $t$ , the derivative  $f'(t)$  or  $df/dt$  or  $v(t)$  is

$$f'(t) = \lim_{\Delta t \rightarrow 0} \frac{f(t + \Delta t) - f(t)}{\Delta t}. \quad (1)$$

The ratio on the right is the average velocity over a short time  $\Delta t$ . The derivative, on the left side, is its limit as the step  $\Delta t$  (*delta t*) approaches zero.

Go slowly and look at each piece. The distance at time  $t + \Delta t$  is  $f(t + \Delta t)$ . The distance at time  $t$  is  $f(t)$ . Subtraction gives the *change in distance*, between those times. We often write  $\Delta f$  for this difference:  $\Delta f = f(t + \Delta t) - f(t)$ . *The average velocity is the ratio  $\Delta f/\Delta t$ —change in distance divided by change in time.*

The limit of the average velocity is the derivative, if this limit exists:

$$\frac{df}{dt} = \lim_{\Delta t \rightarrow 0} \frac{\Delta f}{\Delta t}. \quad (2)$$

This is the neat notation that Leibniz invented:  $\Delta f/\Delta t$  approaches  $df/dt$ . Behind the innocent word “*limit*” is a process that this course will help you understand.

Note that  $\Delta f$  is not  $\Delta$  times  $f$ ! *It is the change in  $f$ .* Similarly  $\Delta t$  is not  $\Delta$  times  $t$ . It is the time step, positive or negative and eventually small. To have a one-letter symbol we replace  $\Delta t$  by  $h$ .

The right sides of (1) and (2) contain average speeds. On the graph of  $f(t)$ , the distance *up* is divided by the distance *across*. That gives the average slope  $\Delta f/\Delta t$ .

The left sides of (1) and (2) are *instantaneous* speeds  $df/dt$ . They give the slope at the instant  $t$ . This is the derivative  $df/dt$  (when  $\Delta t$  and  $\Delta f$  shrink to zero). Look again

## 2.1 The Derivative of a Function

at the calculation for  $f(t) = t^2$ :

$$\frac{\Delta f}{\Delta t} = \frac{f(t + \Delta t) - f(t)}{\Delta t} = \frac{t^2 + 2t \Delta t + (\Delta t)^2 - t^2}{\Delta t} = 2t + \Delta t. \quad (3)$$

Important point: Those steps are taken before  $\Delta t$  goes to zero. *If we set  $\Delta t = 0$  too soon, we learn nothing.* The ratio  $\Delta f/\Delta t$  becomes 0/0 (which is meaningless). The numbers  $\Delta f$  and  $\Delta t$  must approach zero together, not separately. Here their ratio is  $2t + \Delta t$ , the average speed.

To repeat: Success came by writing out  $(t + \Delta t)^2$  and subtracting  $t^2$  and dividing by  $\Delta t$ . Then and only then can we approach  $\Delta t = 0$ . The limit is the derivative  $2t$ .

There are several new things in formulas (1) and (2). Some are easy but important, others are more profound. The idea of a function we will come back to, and the definition of a limit. But the notations can be discussed right away. They are used constantly and you also need to know how to read them aloud:

$f(t)$  = “ $f$  of  $t$ ” = the value of the function  $f$  at time  $t$

$\Delta t$  = “delta  $t$ ” = the time step forward or backward from  $t$

$f(t + \Delta t)$  = “ $f$  of  $t$  plus delta  $t$ ” = the value of  $f$  at time  $t + \Delta t$

$\Delta f$  = “delta  $f$ ” = the change  $f(t + \Delta t) - f(t)$

$\Delta f/\Delta t$  = “delta  $f$  over delta  $t$ ” = the average velocity

$f'(t)$  = “ $f$  prime of  $t$ ” = the value of the derivative at time  $t$

$df/dt$  = “ $df$   $d$   $t$ ” = the same as  $f'$  (the instantaneous velocity)

$\lim_{\Delta t \rightarrow 0}$  = “limit as delta  $t$  goes to zero” = the process that starts with numbers  $\Delta f/\Delta t$  and produces the number  $df/dt$ .

From those last words you see what lies behind the notation  $df/dt$ . The symbol  $\Delta t$  indicates a nonzero (usually short) length of time. The symbol  $dt$  indicates an infinitesimal (even shorter) length of time. Some mathematicians work separately with  $df$  and  $dt$ , and  $df/dt$  is their ratio. For us  $df/dt$  is a single notation (don't cancel  $d$  and don't cancel  $\Delta$ ). The derivative  $df/dt$  is the limit of  $\Delta f/\Delta t$ . When that notation  $df/dt$  is awkward, use  $f'$  or  $v$ .

**Remark** The notation hides one thing we should mention. The time step can be negative just as easily as positive. We can compute the average  $\Delta f/\Delta t$  over a time interval *before* the time  $t$ , instead of after. This ratio also approaches  $df/dt$ .

The notation also hides another thing: *The derivative might not exist.* The averages  $\Delta f/\Delta t$  might not approach a limit (it has to be the same limit going forward and backward from time  $t$ ). In that case  $f'(t)$  is not defined. At that instant there is no clear reading on the speedometer. This will happen in Example 2.

**EXAMPLE 1** (Constant velocity  $V = 2$ ) The distance  $f$  is  $V$  times  $t$ . The distance at time  $t + \Delta t$  is  $V$  times  $t + \Delta t$ . **The difference  $\Delta f$  is  $V$  times  $\Delta t$ :**

$$\frac{\Delta f}{\Delta t} = \frac{V\Delta t}{\Delta t} = V \text{ so the limit is } \frac{df}{dt} = V.$$

The derivative of  $Vt$  is  $V$ . The derivative of  $2t$  is 2. The averages  $\Delta f/\Delta t$  are always  $V = 2$ , in this exceptional case of a constant velocity.

**EXAMPLE 2** Constant velocity 2 up to time  $t = 3$ , then stop.

For small times we still have  $f(t) = 2t$ . But after the stopping time, the distance is fixed at  $f(t) = 6$ . The graph is flat beyond time 3. Then  $f(t + \Delta t) = f(t)$  and  $\Delta f = 0$  and **the derivative of a constant function is zero**:

$$t > 3: \quad f'(t) = \lim_{\Delta t \rightarrow 0} \frac{f(t + \Delta t) - f(t)}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{0}{\Delta t} = 0. \quad (4)$$

In this example **the derivative is not defined at the instant when  $t = 3$** . The velocity falls suddenly from 2 to zero. The ratio  $\Delta f/\Delta t$  depends, at that special moment, on whether  $\Delta t$  is positive or negative. The average velocity *after* time  $t = 3$  is zero. The average velocity *before* that time is 2. When the graph of  $f$  has a corner, the graph of  $v$  has a **jump**. It is a **step function**.

One new part of that example is the notation ( $df/dt$  or  $f'$  instead of  $v$ ). Please look also at the third figure. It shows how the function takes  $t$  (on the left) to  $f(t)$ . Especially it shows  $\Delta t$  and  $\Delta f$ . At the start,  $\Delta f/\Delta t$  is 2. After the stop at  $t = 3$ , all  $t$ 's go to the same  $f(t) = 6$ . So  $\Delta f = 0$  and  $df/dt = 0$ .

**Fig. 2.1** The derivative is 2 then 0. It does not exist at  $t = 3$ .

### THE DERIVATIVE OF $1/t$

Here is a completely different slope, for the “demand function”  $f(t) = 1/t$ . The demand is  $1/t$  when the price is  $t$ . A high price  $t$  means a low demand  $1/t$ . Increasing the price reduces the demand. The calculus question is: **How quickly does  $1/t$  change when  $t$  changes?** The “marginal demand” is the slope of the demand curve.

The big thing is to find the derivative of  $1/t$  once and for all. It is  $-1/t^2$ .

**EXAMPLE 3**  $f(t) = \frac{1}{t}$  has  $\Delta f = \frac{1}{t + \Delta t} - \frac{1}{t}$ . This equals  $\frac{t - (t + \Delta t)}{t(t + \Delta t)} = \frac{-\Delta t}{t(t + \Delta t)}$ .

Divide by  $\Delta t$  and let  $\Delta t \rightarrow 0$ :  $\frac{\Delta f}{\Delta t} = \frac{-1}{t(t + \Delta t)}$  approaches  $\frac{df}{dt} = \frac{-1}{t^2}$ .

Line 1 is algebra, line 2 is calculus. The first step in line 1 subtracts  $f(t)$  from  $f(t + \Delta t)$ . The difference is  $1/(t + \Delta t)$  minus  $1/t$ . The common denominator is  $t$  times  $t + \Delta t$ —this makes the algebra possible. We can't set  $\Delta t = 0$  in line 2, until we have divided by  $\Delta t$ .

The average is  $\Delta f/\Delta t = -1/t(t + \Delta t)$ . Now set  $\Delta t = 0$ . The derivative is  $-1/t^2$ . Section 2.4 will discuss the first of many cases when substituting  $\Delta t = 0$  is not possible, and the idea of a limit has to be made clearer.

## 2.1 The Derivative of a Function

**Fig. 2.2** Average slope is  $-\frac{1}{6}$ , true slope is  $-\frac{1}{4}$ . Increase in  $t$  produces decrease in  $f$ .

Check the algebra at  $t = 2$  and  $t + \Delta t = 3$ . The demand  $1/t$  drops from  $1/2$  to  $1/3$ . The difference is  $\Delta f = -1/6$ , which agrees with  $-1/(2)(3)$  in line 1. As the steps  $\Delta f$  and  $\Delta t$  get smaller, their ratio approaches  $-1/(2)(2) = -1/4$ .

**This derivative is negative.** The function  $1/t$  is *decreasing*, and  $\Delta f$  is below zero. The graph is going *downward* in Figure 2.2, and its slope is negative:

*An increasing  $f(t)$  has positive slope. A decreasing  $f(t)$  has negative slope.*

The slope  $-1/t^2$  is very negative for small  $t$ . A price increase severely cuts demand.

The next figure makes a small but important point. There is nothing sacred about  $t$ . Other letters can be used—especially  $x$ . A quantity can depend on **position instead of time**. The height changes as we go west. The area of a square changes as the side changes. Those are not affected by the passage of time, and there is no reason to use  $t$ . You will often see  $y = f(x)$ , with  $x$  across and  $y$  up—connected by a function  $f$ .

Similarly,  $f$  is not the only possibility. Not every function is named  $f$ ! That letter is useful because it stands for the word function—but we are perfectly entitled to write  $y(x)$  or  $y(t)$  instead of  $f(x)$  or  $f(t)$ . The distance up is a function of the distance across. This relationship “ $y$  of  $x$ ” is all-important to mathematics.

The slope is also a function. Calculus is about two functions,  $y(x)$  and  $dy/dx$ .

**Question** If we add 1 to  $y(x)$ , what happens to the slope? *Answer* Nothing.

**Question** If we add 1 to the slope, what happens to the height? *Answer* \_\_\_\_\_.

The symbols  $t$  and  $x$  represent **independent variables**—they take any value they want to (in the domain). Once they are set,  $f(t)$  and  $y(x)$  are determined. Thus  $f$  and  $y$  represent **dependent variables**—they *depend* on  $t$  and  $x$ . A change  $\Delta t$  produces a

**Fig. 2.3** The derivative of  $1/t$  is  $-1/t^2$ . The slope of  $1/x$  is  $-1/x^2$ .

change  $\Delta f$ . A change  $\Delta x$  produces  $\Delta y$ . The independent variable goes inside the parentheses in  $f(t)$  and  $y(x)$ . It is not the letter that matters, it is the idea:

independent variable  $t$  or  $x$   
dependent variable  $f$  or  $g$  or  $y$  or  $z$  or  $u$   
derivative  $df/dt$  or  $df/dx$  or  $dy/dx$  or ...

The derivative  $dy/dx$  comes from [change in  $y$ ] divided by [change in  $x$ ]. The time step becomes a space step, forward or backward. The slope is the rate at which  $y$  changes with  $x$ . *The derivative of a function is its “rate of change.”*

I mention that physics books use  $x(t)$  for distance. Darn it.

To emphasize the definition of a derivative, here it is again with  $y$  and  $x$ :

$$\frac{\Delta y}{\Delta x} = \frac{y(x + \Delta x) - y(x)}{\Delta x} = \frac{\text{distance up}}{\text{distance across}} \quad \frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = y'(x).$$

The notation  $y'(x)$  pins down the point  $x$  where the slope is computed. In  $dy/dx$  that extra precision is omitted. This book will try for a reasonable compromise between logical perfection and ordinary simplicity. The notation  $dy/dx(x)$  is not good;  $y'(x)$  is better; when  $x$  is understood it need not be written in parentheses.

You are allowed to say that the function is  $y = x^2$  and the derivative is  $y' = 2x$ —even if the strict notation requires  $y(x) = x^2$  and  $y'(x) = 2x$ . You can even say that the function is  $x^2$  and its derivative is  $2x$  and its *second derivative* is 2—provided everybody knows what you mean.

Here is an example. It is a little early and optional but terrific. You get excellent practice with letters and symbols, and out come new derivatives.

**EXAMPLE 4** If  $u(x)$  has slope  $du/dx$ , what is the slope of  $f(x) = (u(x))^2$ ?

From the derivative of  $x^2$  this will give the derivative of  $x^4$ . In that case  $u = x^2$  and  $f = x^4$ . First point: *The derivative of  $u^2$  is not  $(du/dx)^2$ .* We do not square the derivative  $2x$ . To find the “square rule” we start as we have to—with  $\Delta f = f(x + \Delta x) - f(x)$ :

$$\Delta f = (u(x + \Delta x))^2 - (u(x))^2 = [u(x + \Delta x) + u(x)][u(x + \Delta x) - u(x)].$$

This algebra puts  $\Delta f$  in a convenient form. We factored  $a^2 - b^2$  into  $[a + b]$  times  $[a - b]$ . Notice that we don’t have  $(\Delta u)^2$ . We have  $\Delta f$ , the change in  $u^2$ . Now divide by  $\Delta x$  and take the limit:

$$\frac{\Delta f}{\Delta x} = [u(x + \Delta x) + u(x)] \left[ \frac{u(x + \Delta x) - u(x)}{\Delta x} \right] \text{ approaches } 2u(x) \frac{du}{dx}. \quad (5)$$

This is the *square rule*: *The derivative of  $(u(x))^2$  is  $2u(x)$  times  $du/dx$ .* From the derivatives of  $x^2$  and  $1/x$  and  $\sin x$  (all known) the examples give new derivatives.

**EXAMPLE 5** ( $u = x^2$ ) The derivative of  $x^4$  is  $2u du/dx = 2(x^2)(2x) = 4x^3$ .

**EXAMPLE 6** ( $u = 1/x$ ) The derivative of  $1/x^2$  is  $2u du/dx = (2/x)(-1/x^2) = -2/x^3$ .

**EXAMPLE 7** ( $u = \sin x$ ,  $du/dx = \cos x$ ) The derivative of  $u^2 = \sin^2 x$  is  $2 \sin x \cos x$ .

Mathematics is really about ideas. The notation is created to express those ideas. Newton and Leibniz invented calculus independently, and Newton’s friends spent a lot of time proving that he was first. He was, but it was Leibniz who thought of

writing  $dy/dx$ —which caught on. It is the perfect way to suggest the limit of  $\Delta y/\Delta x$ . Newton was one of the great scientists of all time, and calculus was one of the great inventions of all time—but the notation must help. You now can write and speak about the derivative. What is needed is a longer list of functions and derivatives.

---

## 2.1 EXERCISES

---

**Read-through questions**

The derivative is the a of  $\Delta f/\Delta t$  as  $\Delta t$  approaches b. Here  $\Delta f$  equals c. The step  $\Delta t$  can be positive or d. The derivative is written e or f. If  $f(x) = 2x + 3$  and  $\Delta x = 4$  then  $\Delta f =$  g. If  $\Delta x = -1$  then  $\Delta f =$  h. If  $\Delta x = 0$  then  $\Delta f =$  i. The slope is not  $0/0$  but  $df/dx =$  j.

The derivative does not exist where  $f(t)$  has a k and  $v(t)$  has a l. For  $f(t) = 1/t$  the derivative is m. The slope of  $y = 4/x$  is  $dy/dx =$  n. A decreasing function has a o derivative. The p variable is  $t$  or  $x$  and the q variable is  $f$  or  $y$ . The slope of  $y^2$  (is) (is not)  $(dy/dx)^2$ . The slope of  $(u(x))^2$  is r by the square rule. The slope of  $(2x + 3)^2$  is s.

**1** Which of the following numbers (as is) gives  $df/dt$  at time  $t$ ? If in doubt test on  $f(t) = t^2$ .

(a)  $\frac{f(t + \Delta t) - f(t)}{\Delta t}$

(b)  $\lim_{h \rightarrow 0} \frac{f(t + 2h) - f(t)}{2h}$

(c)  $\lim_{\Delta t \rightarrow 0} \frac{f(t - \Delta t) - f(t)}{-\Delta t}$

(d)  $\lim_{t \rightarrow 0} \frac{f(t + \Delta t) - f(t)}{\Delta t}$

**2** Suppose  $f(x) = x^2$ . Compute each ratio and set  $h = 0$ :

(a)  $\frac{f(x + h) - f(x)}{h}$

(b)  $\frac{f(x + 5h) - f(x)}{5h}$

(c)  $\frac{f(x + h) - f(x - h)}{2h}$

(d)  $\frac{f(x + 1) - f(x)}{h}$

**3** For  $f(x) = 3x$  and  $g(x) = 1 + 3x$ , find  $f(4 + h)$  and  $g(4 + h)$  and  $f'(4)$  and  $g'(4)$ . Sketch the graphs of  $f$  and  $g$ —why do they have the same slope?

**4** Find three functions with the same slope as  $f(x) = x^2$ .

**5** For  $f(x) = 1/x$ , sketch the graphs of  $f(x) + 1$  and  $f(x + 1)$ . Which one has the derivative  $-1/x^2$ ?

**6** Choose  $c$  so that the line  $y = x$  is tangent to the parabola  $y = x^2 + c$ . They have the same slope where they touch.

**7** Sketch the curve  $y(x) = 1 - x^2$  and compute its slope at  $x = 3$ .

**8** If  $f(t) = 1/t$ , what is the average velocity between  $t = \frac{1}{2}$  and  $t = 2$ ? What is the average between  $t = \frac{1}{2}$  and  $t = 1$ ? What is the average (to one decimal place) between  $t = \frac{1}{2}$  and  $t = 101/200$ ?

**9** Find  $\Delta y/\Delta x$  for  $y(x) = x + x^2$ . Then find  $dy/dx$ .

**10** Find  $\Delta y/\Delta x$  and  $dy/dx$  for  $y(x) = 1 + 2x + 3x^2$ .

**11** When  $f(t) = 4/t$ , simplify the difference  $f(t + \Delta t) - f(t)$ , divide by  $\Delta t$ , and set  $\Delta t = 0$ . The result is  $f'(t)$ .

**12** Find the derivative of  $1/t^2$  from  $\Delta f(t) = 1/(t + \Delta t)^2 - 1/t^2$ . Write  $\Delta f$  as a fraction with the denominator  $t^2(t + \Delta t)^2$ . Divide the numerator by  $\Delta t$  to find  $\Delta f/\Delta t$ . Set  $\Delta t = 0$ .

**13** Suppose  $f(t) = 7t$  to  $t = 1$ . Afterwards  $f(t) = 7 + 9(t - 1)$ .

(a) Find  $df/dt$  at  $t = \frac{1}{2}$  and  $t = \frac{3}{2}$ .

(b) Why doesn't  $f(t)$  have a derivative at  $t = 1$ ?

**14** Find the derivative of the derivative (the *second derivative*) of  $y = 3x^2$ . What is the third derivative?

**15** Find numbers  $A$  and  $B$  so that the straight line  $y = x$  fits smoothly with the curve  $Y = A + Bx + x^2$  at  $x = 1$ . Smoothly means that  $y = Y$  and  $dy/dx = dY/dx$  at  $x = 1$ .

**16** Find numbers  $A$  and  $B$  so that the horizontal line  $y = 4$  fits smoothly with the curve  $y = A + Bx + x^2$  at the point  $x = 2$ .

**17** True (with reason) or false (with example):

(a) If  $f(t) < 0$  then  $df/dt < 0$ .

(b) The derivative of  $(f(t))^2$  is  $2 df/dt$ .

(c) The derivative of  $2f(t)$  is  $2 df/dt$ .

(d) The derivative is the limit of  $\Delta f$  divided by the limit of  $\Delta t$ .

**18** For  $f(x) = 1/x$  the centered difference  $f(x + h) - f(x - h)$  is  $1/(x + h) - 1/(x - h)$ . Subtract by using the common denominator  $(x + h)(x - h)$ . Then divide by  $2h$  and set  $h = 0$ . Why divide by  $2h$  to obtain the correct derivative?

**19** Suppose  $y = mx + b$  for negative  $x$  and  $y = Mx + B$  for  $x \geq 0$ . The graphs meet if \_\_\_\_\_. The two slopes are \_\_\_\_\_. The slope at  $x = 0$  is \_\_\_\_\_ (what is possible?).

**20** The slope of  $y = 1/x$  at  $x = 1/4$  is  $y' = -1/x^2 = -16$ . At  $h = 1/12$ , which of these ratios is closest to  $-16$ ?

$$\frac{y(x + h) - y(x)}{h} \quad \frac{y(x) - y(x - h)}{h} \quad \frac{y(x + h) - y(x - h)}{2h}$$

**21** Find the average slope of  $y = x^2$  between  $x = x_1$  and  $x = x_2$ . What does this average approach as  $x_2$  approaches  $x_1$ ?

**22** Redraw Figure 2.1 when  $f(t) = 3 - 2t$  for  $t \leq 2$  and  $f(t) = -1$  for  $t \geq 2$ . Include  $df/dt$ .

23 Redraw Figure 2.3 for the function  $y(x) = 1 - (1/x)$ . Include  $dy/dx$ .

24 The limit of  $0/\Delta t$  as  $\Delta t \rightarrow 0$  is not  $0/0$ . Explain.

25 Guess the limits by an informal working rule. Set  $\Delta t = 0.1$  and  $-0.1$  and imagine  $\Delta t$  becoming smaller:

(a)  $\frac{1 + \Delta t}{2 + \Delta t}$

(b)  $\frac{|\Delta t|}{\Delta t}$

(c)  $\frac{\Delta t + (\Delta t)^2}{\Delta t - (\Delta t)^2}$

(d)  $\frac{t + \Delta t}{t - \Delta t}$

\*26 Suppose  $f(x)/x \rightarrow 7$  as  $x \rightarrow 0$ . Deduce that  $f(0) = 0$  and  $f'(0) = 7$ . Give an example other than  $f(x) = 7x$ .

27 What is  $\lim_{x \rightarrow 0} \frac{f(3+x) - f(3)}{x}$  if it exists? What if  $x \rightarrow 1$ ?

**Problems 28–31 use the square rule:**  $d(u^2)/dx = 2u(du/dx)$ .

28 Take  $u = x$  and find the derivative of  $x^2$  (a new way).

29 Take  $u = x^4$  and find the derivative of  $x^8$  (using  $du/dx = 4x^3$ ).

30 If  $u = 1$  then  $u^2 = 1$ . Then  $d1/dx$  is 2 times  $d1/dx$ . How is this possible?

31 Take  $u = \sqrt{x}$ . The derivative of  $u^2 = x$  is  $1 = 2u(du/dx)$ . So what is  $du/dx$ , the derivative of  $\sqrt{x}$ ?

32 The left figure shows  $f(t) = t^2$ . Indicate distances  $f(t + \Delta t)$  and  $\Delta t$  and  $\Delta f$ . Draw lines that have slope  $\Delta f/\Delta t$  and  $f'(t)$ .

33 The right figure shows  $f(x)$  and  $\Delta x$ . Find  $\Delta f/\Delta x$  and  $f'(2)$ .

34 Draw  $f(x)$  and  $\Delta x$  so that  $\Delta f/\Delta x = 0$  but  $f'(x) \neq 0$ .

35 If  $f = u^2$  then  $df/dx = 2u du/dx$ . If  $g = f^2$  then  $dg/dx = 2f df/dx$ . Together those give  $g = u^4$  and  $dg/dx =$  \_\_\_\_\_.

36 **True or false**, assuming  $f(0) = 0$ :

(a) If  $f(x) \leq x$  for all  $x$ , then  $df/dx \leq 1$ .

(b) If  $df/dx \leq 1$  for all  $x$ , then  $f(x) \leq x$ .

37 The graphs show  $\Delta f$  and  $\Delta f/h$  for  $f(x) = x^2$ . Why is  $2x + h$  the equation for  $\Delta f/h$ ? If  $h$  is cut in half, draw in the new graphs.

38 Draw the corresponding graphs for  $f(x) = \frac{1}{2}x$ .

39 Draw  $1/x$  and  $1/(x+h)$  and  $\Delta f/h$ —either by hand with  $h = \frac{1}{2}$  or by computer to show  $h \rightarrow 0$ .

40 For  $y = e^x$ , show on computer graphs that  $dy/dx = y$ .

41 Explain the derivative in your own words.

## 2.2 Powers and Polynomials

This section has two main goals. One is to find the derivatives of  $f(x) = x^3$  and  $x^4$  and  $x^5$  (and more generally  $f(x) = x^n$ ). The *power* or *exponent*  $n$  is at first a positive integer. Later we allow  $x^\pi$  and  $x^{2.2}$  and every  $x^n$ .

The other goal is different. While computing these derivatives, we look ahead to their applications. In using calculus, we meet *equations with derivatives in them*—“*differential equations*.” It is too early to solve those equations. But it is not too early to see the purpose of what we are doing. Our examples come from economics and biology.

With  $n = 2$ , the derivative of  $x^2$  is  $2x$ . With  $n = -1$ , the slope of  $x^{-1}$  is  $-1x^{-2}$ . Those are two pieces in a beautiful pattern, which it will be a pleasure to discover. We begin with  $x^3$  and its derivative  $3x^2$ , before jumping to  $x^n$ .

**EXAMPLE 1** If  $f(x) = x^3$  then  $\Delta f = (x + h)^3 - x^3 = (x^3 + 3x^2h + 3xh^2 + h^3) - x^3$ .

Step 1: Cancel  $x^3$ .

Step 2: Divide by  $h$ .

Step 3:  $h$  goes to zero.

$$\frac{\Delta f}{h} = \frac{3x^2 + 3xh + h^2}{h} \text{ approaches } \frac{df}{dx} = 3x^2.$$

That is straightforward, and you see the crucial step. The power  $(x + h)^3$  yields four separate terms  $x^3 + 3x^2h + 3xh^2 + h^3$ . (Notice 1, 3, 3, 1.) After  $x^3$  is subtracted, we can divide by  $h$ . At the limit ( $h = 0$ ) we have  $3x^2$ .

For  $f(x) = x^n$  the plan is the same. A step of size  $h$  leads to  $f(x + h) = (x + h)^n$ . One reason for algebra is to calculate powers like  $(x + h)^n$ , and if you have forgotten the binomial formula we can recapture its main point. Start with  $n = 4$ :

$$(x + h)(x + h)(x + h)(x + h) = x^4 + \dots + h^4. \quad (1)$$

Multiplying the four  $x$ 's gives  $x^4$ . Multiplying the four  $h$ 's gives  $h^4$ . These are the easy terms, but not the crucial ones. The subtraction  $(x + h)^4 - x^4$  will remove  $x^4$ , and the limiting step  $h \rightarrow 0$  will wipe out  $h^4$  (even after division by  $h$ ). **The products that matter are those with exactly one  $h$** . In Example 1 with  $(x + h)^3$ , this key term was  $3x^2h$ . Division by  $h$  left  $3x^2$ .

*With only one  $h$ , there are  $n$  places it can come from.* Equation (1) has four  $h$ 's in parentheses, and four ways to produce  $x^3h$ . Therefore the key term is  $4x^3h$ . (Division by  $h$  leaves  $4x^3$ .) In general there are  $n$  parentheses and  $n$  ways to produce  $x^{n-1}h$ , so the **binomial formula** contains  $nx^{n-1}h$ :

$$(x + h)^n = x^n + \underline{nx^{n-1}h} + \dots + h^n. \quad (2)$$

**2B** For  $n = 1, 2, 3, 4, \dots$ , the derivative of  $x^n$  is  $nx^{n-1}$ .

Subtract  $x^n$  from (2). Divide by  $h$ . The key term is  $nx^{n-1}$ . The rest disappears as  $h \rightarrow 0$ :

$$\frac{\Delta f}{\Delta x} = \frac{(x + h)^n - x^n}{h} = \frac{nx^{n-1}h + \dots + h^n}{h} \text{ so } \frac{df}{dx} = nx^{n-1}.$$

The terms replaced by the dots involve  $h^2$  and  $h^3$  and higher powers. After dividing by  $h$ , they still have at least one factor  $h$ . All those terms vanish as  $h$  approaches zero.

**EXAMPLE 2**  $(x + h)^4 = x^4 + \underline{4x^3h} + 6x^2h^2 + 4xh^3 + h^4$ . This is  $n = 4$  in detail.

Subtract  $x^4$ , divide by  $h$ , let  $h \rightarrow 0$ . The derivative is  $4x^3$ . The coefficients 1, 4, 6, 4, 1 are in Pascal's triangle below. For  $(x + h)^5$  the next row is 1, 5, 10, ?.

**Remark** The missing terms in the binomial formula (replaced by the dots) contain all the products  $x^{n-j}h^j$ . An  $x$  or an  $h$  comes from each parenthesis. The binomial coefficient “ $n$  choose  $j$ ” is **the number of ways to choose  $j$   $h$ 's out of  $n$  parentheses**. It involves  $n$  factorial, which is  $n(n - 1) \cdots (1)$ . Thus  $5! = 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 = 120$ .

These are numbers that gamblers know and love:

<i>n choose j</i>	$\binom{n}{j} = \frac{n!}{j!(n-j)!}$	1 1 1 2 1 1 3 3 1 1 4 6 4 1	Pascal's triangle <i>n=3</i> <i>n=4</i>

In the last row, the coefficient of  $x^3 h$  is  $4!/1!3! = 4 \cdot 3 \cdot 2 \cdot 1 / 1 \cdot 3 \cdot 2 \cdot 1 = 4$ . For the  $x^2 h^2$  term, with  $j = 2$ , there are  $4 \cdot 3 \cdot 2 \cdot 1 / 2 \cdot 1 \cdot 2 \cdot 1 = 6$  ways to choose two  $h$ 's. Notice that  $1 + 4 + 6 + 4 + 1$  equals 16, which is  $2^4$ . Each row of Pascal's triangle adds to a power of 2.

Choosing 6 numbers out of 49 in a lottery, the odds are  $49 \cdot 48 \cdot 47 \cdot 46 \cdot 45 \cdot 44 / 6!$  to 1. That number is  $N = \text{"49 choose 6"} = 13,983,816$ . It is the coefficient of  $x^{43} h^6$  in  $(x+h)^{49}$ . If  $\lambda$  times  $N$  tickets are bought, the expected number of winners is  $\lambda$ . The chance of no winner is  $e^{-\lambda}$ . The chance of one winner is  $\lambda e^{-\lambda}$ . See Section 8.4.

Florida's lottery in September 1990 (these rules) had six winners out of 109,163,978 tickets.

### DERIVATIVES OF POLYNOMIALS

Now we have an infinite list of functions and their derivatives:

$$x \ x^2 \ x^3 \ x^4 \ x^5 \dots \quad 1 \ 2x \ 3x^2 \ 4x^3 \ 5x^4 \dots$$

*The derivative of  $x^n$  is  $n$  times the next lower power  $x^{n-1}$ . That rule extends beyond these integers 1, 2, 3, 4, 5 to all powers:*

$$\begin{aligned} f = 1/x &\text{ has } f' = -1/x^2; && \text{Example 3 of Section 2.1 } (n = -1) \\ f = 1/x^2 &\text{ has } f' = -2/x^3; && \text{Example 6 of Section 2.1 } (n = -2) \\ f = \sqrt{x} &\text{ has } f' = \frac{1}{2}x^{-1/2}; && \text{true but not yet checked } (n = \frac{1}{2}) \end{aligned}$$

Remember that  $x^{-2}$  means  $1/x^2$  and  $x^{-1/2}$  means  $1/\sqrt{x}$ . Negative powers lead to decreasing functions, approaching zero as  $x$  gets large. Their slopes have minus signs.

**Question** What are the derivatives of  $x^{10}$  and  $x^{2.2}$  and  $x^{-1/2}$ ?

Answer  $10x^9$  and  $2.2x^{1.2}$  and  $-\frac{1}{2}x^{-3/2}$ . Maybe  $(x+h)^{2.2}$  is a little unusual. Pascal's triangle can't deal with this fractional power, but the formula stays firm: *After  $x^{2.2}$  comes  $2.2x^{1.2}h$ .* The complete binomial formula is in Section 10.5.

That list is a good start, but plenty of functions are left. What comes next is really simple. A tremendous number of new functions are "linear combinations" like

$$f(x) = 6x^3 \quad \text{or} \quad 6x^3 + \frac{1}{2}x^2 \quad \text{or} \quad 6x^3 - \frac{1}{2}x^2.$$

What are their derivatives? The answers are known for  $x^3$  and  $x^2$ , and we want to multiply by 6 or divide by 2 or add or subtract. *Do the same to the derivatives:*

$$f'(x) = 18x^2 \quad \text{or} \quad 18x^2 + x \quad \text{or} \quad 18x^2 - x.$$

**2C** The derivative of  $c$  times  $f(x)$  is  $c$  times  $f'(x)$ .

**2D** The derivative of  $f(x) + g(x)$  is  $f'(x) + g'(x)$ .

The number  $c$  can be any constant. We can add (or subtract) any functions. The rules allow any combination of  $f$  and  $g$ : *The derivative of  $9f(x) - 7g(x)$  is  $9f'(x) - 7g'(x)$ .*

The reasoning is direct. When  $f(x)$  is multiplied by  $c$ , so is  $f(x + h)$ . The difference  $\Delta f$  is also multiplied by  $c$ . All averages  $\Delta f/h$  contain  $c$ , so their limit is  $cf'$ . The only incomplete step is the last one (the limit). *We still have to say what “limit” means.*

Rule 2D is similar. Adding  $f + g$  means adding  $\Delta f + \Delta g$ . Now divide by  $h$ . In the limit as  $h \rightarrow 0$  we reach  $f' + g'$ —because a limit of sums is a sum of limits. Any example is easy and so is the proof—it is the definition of limit that needs care (Section 2.6).

**You can now find the derivative of every polynomial.** A “polynomial” is a combination of  $1$ ,  $x$ ,  $x^2$ , ...,  $x^n$ —for example  $9 + 2x - x^5$ . That particular polynomial has slope  $2 - 5x^4$ . Note that the derivative of  $9$  is zero! A constant just raises or lowers the graph, without changing its slope. It alters the mileage before starting the car.

The disappearance of constants is one of the nice things in differential calculus. The reappearance of those constants is one of the headaches in integral calculus. When you find  $v$  from  $f$ , the starting mileage doesn’t matter. The constant in  $f$  has no effect on  $v$ . ( $\Delta f$  is measured by a trip meter;  $\Delta t$  comes from a stopwatch.) To find distance from velocity, you need to know the mileage at the start.

### A LOOK AT DIFFERENTIAL EQUATIONS (FIND $y$ FROM $dy/dx$ )

We know that  $y = x^3$  has the derivative  $dy/dx = 3x^2$ . Starting with the function, we found its slope. Now reverse that process. **Start with the slope and find the function.** This is what science does all the time—and it seems only reasonable to say so.

Begin with  $dy/dx = 3x^2$ . The slope is given, the function  $y$  is not given.

**Question** Can you go backward to reach  $y = x^3$ ?

**Answer** Almost but not quite. You are only entitled to say that  $y = x^3 + C$ . The constant  $C$  is the starting value of  $y$  (when  $x = 0$ ). Then the **differential equation**  $dy/dx = 3x^2$  is solved.

Every time you find a derivative, you can go backward to solve a differential equation. The function  $y = x^2 + x$  has the slope  $dy/dx = 2x + 1$ . In reverse, the slope  $2x + 1$  produces  $x^2 + x$ —and all the other functions  $x^2 + x + C$ , shifted up and down. After going from distance  $f$  to velocity  $v$ , we return to  $f + C$ . But there is a lot more to differential equations. Here are two crucial points:

1. We reach  $dy/dx$  by way of  $\Delta y/\Delta x$ , but we have no system to go backward. With  $dy/dx = (\sin x)/x$  we are lost. What function has this derivative?
2. Many equations have the same solution  $y = x^3$ . Economics has  $dy/dx = 3y/x$ . Geometry has  $dy/dx = 3y^{2/3}$ . These equations involve  $y$  as well as  $dy/dx$ . Function and slope are mixed together! This is typical of differential equations.

*To summarize:* Chapters 2–4 compute and use derivatives. Chapter 5 goes in reverse. Integral calculus discovers the function from its slope. Given  $dy/dx$  we find  $y(x)$ . Then Chapter 6 solves the differential equation  $dy/dt = y$ , function mixed with slope. Calculus moves from *derivatives* to *integrals* to *differential equations*.

This discussion of the purpose of calculus should mention a specific example. Differential equations are applied to an epidemic (like AIDS). In most epidemics the number of cases grows exponentially. The peak is quickly reached by  $e^t$ , and the epidemic dies down. Amazingly, exponential growth is not happening with AIDS—the best fit to the data through 1988 is a **cubic polynomial** (*Los Alamos Science*, 1989):

The number of cases fits a cubic within 2%:  $y = 174.6(t - 1981.2)^3 + 340$ .

This is dramatically different from other epidemics. Instead of  $dy/dt = y$  we have  $dy/dt = 3y/t$ . Before this book is printed, we may know what has been preventing  $e^t$  (fortunately). Eventually the curve will turn away from a cubic—I hope that mathematical models will lead to knowledge that saves lives.

*Added in proof:* In 1989 the curve for the U.S. dropped from  $t^3$  to  $t^2$ .

### MARGINAL COST AND ELASTICITY IN ECONOMICS

First point about economics: The *marginal* cost and *marginal* income are crucially important. The average cost of making automobiles may be \$10,000. But it is the \$8000 cost of the *next car* that decides whether Ford makes it. "The average describes the past, the marginal predicts the future." For bank deposits or work hours or wheat, which come in smaller units, the amounts are continuous variables. Then the word "marginal" says one thing: *Take the derivative.*†

The average pay over all the hours we ever worked may be low. We wouldn't work another hour for that! This average is rising, but the pay for each additional hour rises faster—possibly it jumps. When \$10/hour increases to \$15/hour after a 40-hour week, a 50-hour week pays \$550. The average income is \$11/hour. The marginal income is \$15/hour—the overtime rate.

Concentrate next on cost. Let  $y(x)$  be the cost of producing  $x$  tons of steel. The cost of  $x + \Delta x$  tons is  $y(x + \Delta x)$ . The extra cost is the difference  $\Delta y$ . Divide by  $\Delta x$ , the number of extra tons. The ratio  $\Delta y/\Delta x$  is *the average cost per extra ton*. When  $\Delta x$  is an ounce instead of a ton, we are near the marginal cost  $dy/dx$ .

Example: When the cost is  $x^2$ , the average cost is  $x^2/x = x$ . The marginal cost is  $2x$ . Figure 2.4 has increasing slope—an example of "diminishing returns to scale."

Fig. 2.4 Marginal exceeds average. Constant elasticity  $E = \pm 1$ . Perfectly elastic to perfectly inelastic ( $\Gamma$  curve).

This raises another point about economics. The units are arbitrary. In yen per kilogram the numbers look different. The way to correct for arbitrary units is to work with *percentage change* or *relative change*. An increase of  $\Delta x$  tons is a relative increase of  $\Delta x/x$ . A cost increase  $\Delta y$  is a relative increase of  $\Delta y/y$ . Those are *dimensionless*, the same in tons/tons or dollars/dollars or yen/yen.

A third example is *the demand*  $y$  at *price*  $x$ . Now  $dy/dx$  is negative. But again the units are arbitrary. The demand is in liters or gallons, the price is in dollars or pesos.

†These paragraphs show how calculus applies to economics. You do *not* have to be an economist to understand them. Certainly the author is not, probably the instructor is not, possibly the student is not. We can all use  $dy/dx$ .

Relative changes are better. When the price goes up by 10%, the demand may drop by 5%. If that ratio stays the same for small increases, *the elasticity of demand is  $\frac{1}{2}$* .

Actually this number should be  $-\frac{1}{2}$ . The price rose, the demand dropped. In our definition, the elasticity will be  $-\frac{1}{2}$ . In conversation between economists the minus sign is left out (I hope not forgotten).

**DEFINITION** The elasticity of the demand function  $y(x)$  is

$$E(x) = \lim_{\Delta x \rightarrow 0} \frac{\Delta y/y}{\Delta x/x} = \frac{dy/dx}{y/x}. \quad (3)$$

*Elasticity is “marginal” divided by “average.”*  $E(x)$  is also relative change in  $y$  divided by relative change in  $x$ . Sometimes  $E(x)$  is the same at all prices—this important case is discussed below.

**EXAMPLE 1** Suppose the demand is  $y = c/x$  when the price is  $x$ . The derivative  $dy/dx = -c/x^2$  comes from calculus. The division  $y/x = c/x^2$  is only algebra. *The ratio is  $E = -1$ :*

*For the demand  $y = c/x$ , the elasticity is  $(-c/x^2)/(c/x^2) = -1$ .*

All demand curves are compared with this one. The demand is *inelastic* when  $|E| < 1$ . It is *elastic* when  $|E| > 1$ . The demand  $20/\sqrt{x}$  is inelastic ( $E = -\frac{1}{2}$ ), while  $x^{-3}$  is elastic ( $E = -3$ ). *The power  $y = cx^n$ , whose derivative we know, is the function with constant elasticity  $n$ :*

$$\text{if } y = cx^n \text{ then } dy/dx = cnx^{n-1} \text{ and } E = cnx^{n-1}/(cx^n/x) = n.$$

It is because  $y = cx^n$  sets the standard that we could come so early to economics.

In the special case when  $y = c/x$ , consumers spend the same at all prices. Price  $x$  times quantity  $y$  remains constant at  $xy = c$ .

**EXAMPLE 2** The supply curve has  $E > 0$ —supply increases with price. Now the baseline case is  $y = cx$ . The slope is  $c$  and the average is  $y/x = c$ . *The elasticity is  $E = c/c = 1$ .*

Compare  $E = 1$  with  $E = 0$  and  $E = \infty$ . A constant supply is “perfectly inelastic.” The power  $n$  is zero and the slope is zero:  $y = c$ . No more is available when the harvest is over. Whatever the price, the farmer cannot suddenly grow more wheat. Lack of elasticity makes farm economics difficult.

The other extreme  $E = \infty$  is “perfectly elastic.” The supply is unlimited at a fixed price  $x$ . Once this seemed true of water and timber. In reality the steep curve  $x = \text{constant}$  is leveling off to a flat curve  $y = \text{constant}$ . Fixed price is changing to fixed supply,  $E = \infty$  is becoming  $E = 0$ , and the supply of water follows a “gamma curve” shaped like  $\Gamma$ .

**EXAMPLE 3** Demand is an increasing function of *income*—more income, more demand. The *income elasticity* is  $E(I) = (dy/dI)/(y/I)$ . A luxury has  $E > 1$  (elastic). Doubling your income more than doubles the demand for caviar. A necessity has  $E < 1$  (inelastic). The demand for bread does not double. Please recognize how the central ideas of calculus provide a language for the central ideas of economics.

**Important note on supply = demand** This is the basic equation of microeconomics. Where the supply curve meets the demand curve, the economy finds the equilibrium price. *Supply = demand assumes perfect competition.* With many suppliers, no one can raise the price. If someone tries, the customers go elsewhere.

The opposite case is a **monopoly**—no competition. Instead of many small producers of wheat, there is one producer of electricity. An airport is a monopolist (and maybe the National Football League). If the price is raised, some demand remains.

**Price fixing** occurs when several producers act like a monopoly—which antitrust laws try to prevent. The price is not set by supply = demand. The calculus problem is different—to **maximize profit**. Section 3.2 locates the maximum where the marginal profit (the slope!) is zero.

**Question on income elasticity** From an income of \$10,000 you save \$500. The income elasticity of savings is  $E = 2$ . Out of the next dollar what fraction do you save?

**Answer** The savings is  $y = cx^2$  because  $E = 2$ . The number  $c$  must give  $500 = c(10,000)^2$ , so  $c$  is  $5 \cdot 10^{-6}$ . Then the slope  $dy/dx$  is  $2cx = 10 \cdot 10^{-6} \cdot 10^4 = \frac{1}{10}$ . This is the marginal savings, ten cents on the dollar. **Average savings is 5%, marginal savings is 10%, and  $E = 2$ .**

## 2.2 EXERCISES

### Read-through questions

The derivative of  $f = x^4$  is  $f' = \underline{\text{a}}$ . That comes from expanding  $(x+h)^4$  into the five terms  $\underline{\text{b}}$ . Subtracting  $x^4$  and dividing by  $h$  leaves the four terms  $\underline{\text{c}}$ . This is  $\Delta f/h$ , and its limit is  $\underline{\text{d}}$ .

The derivative of  $f = x^n$  is  $f' = \underline{\text{e}}$ . Now  $(x+h)^n$  comes from the  $\underline{\text{f}}$  theorem. The terms to look for are  $x^{n-1}h$ , containing only one  $\underline{\text{g}}$ . There are  $\underline{\text{h}}$  of those terms, so  $(x+h)^n = x^n + \underline{\text{i}} + \dots$ . After subtracting  $\underline{\text{j}}$  and dividing by  $h$ , the limit of  $\Delta f/h$  is  $\underline{\text{k}}$ . The coefficient of  $x^{n-j}h^j$ , not needed here, is “ $n$  choose  $j$ ” =  $\underline{\text{l}}$ , where  $n!$  means  $\underline{\text{m}}$ .

The derivative of  $x^{-2}$  is  $\underline{\text{n}}$ . The derivative of  $x^{1/2}$  is  $\underline{\text{o}}$ . The derivative of  $3x + (1/x)$  is  $\underline{\text{p}}$ , which uses the following rules: The derivative of  $3f(x)$  is  $\underline{\text{q}}$  and the derivative of  $f(x) + g(x)$  is  $\underline{\text{r}}$ . Integral calculus recovers  $\underline{\text{s}}$  from  $dy/dx$ . If  $dy/dx = x^4$  then  $y(x) = \underline{\text{t}}$ .

1 Starting with  $f = x^6$ , write down  $f'$  and then  $f''$ . (This is “ $f$  double prime,” the derivative of  $f'$ .) After \_\_\_\_\_ derivatives of  $x^6$  you reach a constant. What constant?

2 Find a function that has  $x^6$  as its derivative.

**Find the derivatives of the functions in 3–10. Even if  $n$  is negative or a fraction, the derivative of  $x^n$  is  $nx^{n-1}$ .**

3  $x^2 + 7x + 5$

4  $1 + (7/x) + (5/x^2)$

5  $1 + x + x^2 + x^3 + x^4$

6  $(x^2 + 1)^2$

7  $x^n + x^{-n}$

8  $x^n/n!$

9  $1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4$

10  $\frac{2}{3}x^{3/2} + \frac{2}{5}x^{5/2}$

11 Name two functions with  $df/dx = 1/x^2$ .

12 **Find the mistake:**  $x^2$  is  $x + x + \dots + x$  (with  $x$  terms). Its derivative is  $1 + 1 + \dots + 1$  (also  $x$  terms). So the derivative of  $x^2$  seems to be  $x$ .

13 What are the derivatives of  $3x^{1/3}$  and  $-3x^{-1/3}$  and  $(3x^{1/3})^{-1}$ ?

14 The slope of  $x + (1/x)$  is zero when  $x = \underline{\text{_____}}$ . What does the graph do at that point?

15 Draw a graph of  $y = x^3 - x$ . Where is the slope zero?

16 If  $df/dx$  is negative, is  $f(x)$  always negative? Is  $f(x)$  negative for large  $x$ ? If you think otherwise, give examples.

17 A rock thrown upward with velocity 16 ft/sec reaches height  $f = 16t - 16t^2$  at time  $t$ .

(a) Find its average speed  $\Delta f/\Delta t$  from  $t = 0$  to  $t = \frac{1}{2}$ .

(b) Find its average speed  $\Delta f/\Delta t$  from  $t = \frac{1}{2}$  to  $t = 1$ .

(c) What is  $df/dt$  at  $t = \frac{1}{2}$ ?

18 When  $f$  is in feet and  $t$  is in seconds, what are the units of  $f'$  and its derivative  $f''$ ? In  $f = 16t - 16t^2$ , the first 16 is ft/sec but the second 16 is \_\_\_\_\_.

19 Graph  $y = x^3 + x^2 - x$  from  $x = -2$  to  $x = 2$  and estimate where it is decreasing. Check the transition points by solving  $dy/dx = 0$ .

20 At a point where  $dy/dx = 0$ , what is special about the graph of  $y(x)$ ? Test case:  $y = x^2$ .

21 Find the slope of  $y = \sqrt{x}$  by algebra (then  $h \rightarrow 0$ ):

$$\frac{\Delta y}{h} = \frac{\sqrt{x+h} - \sqrt{x}}{h} = \frac{\sqrt{x+h} - \sqrt{x}}{h} \cdot \frac{\sqrt{x+h} + \sqrt{x}}{\sqrt{x+h} + \sqrt{x}}.$$

22 Imitate Problem 21 to find the slope of  $y = 1/\sqrt{x}$ .

- 23** Complete Pascal's triangle for  $n = 5$  and  $n = 6$ . Why do the numbers across each row add to  $2^n$ ?
- 24** Complete  $(x+h)^5 = x^5 + \underline{\hspace{2cm}}$ . What are the binomial coefficients  $\binom{5}{1}$  and  $\binom{5}{2}$  and  $\binom{5}{3}$ ?

## 2.3 The Slope and the Tangent Line

Chapter 1 started with straight line graphs. The velocity was constant (at least piecewise). The distance function was linear. Now we are facing polynomials like  $x^3 - 2$  or  $x^4 - x^2 + 3$ , with other functions to come soon. Their graphs are definitely curved. Most functions are not close to linear—except if you focus all your attention near a single point. That is what we will do.

**Over a very short range a curve looks straight.** Look through a microscope, or zoom in with a computer, and there is no doubt. The graph of distance versus time becomes nearly linear. Its slope is the velocity at that moment. We want to find the line that the graph stays closest to—the “**tangent line**”—before it curves away.

The tangent line is easy to describe. We are at a particular point on the graph of  $y = f(x)$ . At that point  $x$  equals  $a$  and  $y$  equals  $f(a)$  and the slope equals  $f'(a)$ . **The tangent line goes through that point  $x = a$ ,  $y = f(a)$  with that slope  $m = f'(a)$ .** Figure 2.5 shows the line more clearly than any equation, but we have to turn the geometry into algebra. We need the equation of the line.

**EXAMPLE 1** Suppose  $y = x^4 - x^2 + 3$ . At the point  $x = a = 1$ , the height is  $y = f(a) = 3$ . The slope is  $dy/dx = 4x^3 - 2x$ . At  $x = 1$  the slope is  $4 - 2 = 2$ . That is  $f'(a)$ :

**The numbers  $x = 1$ ,  $y = 3$ ,  $dy/dx = 2$  determine the tangent line.**

*The equation of the tangent line is  $y - 3 = 2(x - 1)$ , and this section explains why.*

**Fig. 2.5** The tangent line has the same slope 2 as the curve (especially after zoom).

### THE EQUATION OF A LINE

A straight line is determined by two conditions. We know the line if we know two of its points. (We still have to write down the equation.) Also, if we know **one point and the slope**, the line is set. That is the situation for the tangent line, which has a known slope at a known point:

1. The equation of a line has the form  $y = mx + b$
2. The number  $m$  is the slope of the line, because  $dy/dx = m$
3. The number  $b$  adjusts the line to go through the required point.

I will take those one at a time—first  $y = mx + b$ , then  $m$ , then  $b$ .

1. The graph of  $y = mx + b$  is not curved. How do we know? For the specific example  $y = 2x + 1$ , take two points whose coordinates  $x, y$  satisfy the equation:

$$x = 0, y = 1 \quad \text{and} \quad x = 4, y = 9 \quad \text{both satisfy} \quad y = 2x + 1.$$

Those points  $(0, 1)$  and  $(4, 9)$  lie on the graph. The point halfway between has  $x = 2$  and  $y = 5$ . That point also satisfies  $y = 2x + 1$ . **The halfway point is on the graph.** If we subdivide again, the midpoint between  $(0, 1)$  and  $(2, 5)$  is  $(1, 3)$ . This also has  $y = 2x + 1$ . The graph contains all halfway points and must be straight.

2. What is the correct slope  $m$  for the tangent line? In our example it is  $m = f'(a) = 2$ . **The curve and its tangent line have the same slope at the crucial point:**  $dy/dx = 2$ .

Allow me to say in another way why the line  $y = mx + b$  has slope  $m$ . At  $x = 0$  its height is  $y = b$ . At  $x = 1$  its height is  $y = m + b$ . The graph has gone one unit across ( $0$  to  $1$ ) and  $m$  units up ( $b$  to  $m + b$ ). The whole idea is

$$\text{slope} = \frac{\text{distance up}}{\text{distance across}} = \frac{m}{1}. \quad (1)$$

Each unit across means  $m$  units up, to  $2m + b$  or  $3m + b$ . A straight line keeps a constant slope, whereas the slope of  $y = x^4 - x^2 + 3$  equals 2 only at  $x = 1$ .

3. Finally we decide on  $b$ . The tangent line  $y = 2x + b$  must go through  $x = 1$ ,  $y = 3$ . Therefore  $b = 1$ . With letters instead of numbers,  $y = mx + b$  leads to  $f(a) = ma + b$ . So we know  $b$ :

**2E** The equation of the tangent line has  $b = f(a) - ma$ :

$$y = mx + f(a) - ma \quad \text{or} \quad y - f(a) = m(x - a). \quad (2)$$

That last form is the best. You see immediately what happens at  $x = a$ . The factor  $x - a$  is zero. Therefore  $y = f(a)$  as required. This is the **point-slope form** of the equation, and we use it constantly:

$$y - 3 = 2(x - 1) \quad \text{or} \quad \frac{y - 3}{x - 1} = \frac{\text{distance up}}{\text{distance across}} = \text{slope } 2.$$

**EXAMPLE 2** The curve  $y = x^3 - 2$  goes through  $y = 6$  when  $x = 2$ . At that point  $dy/dx = 3x^2 = 12$ . The point-slope equation of the tangent line uses 2 and 6 and 12:

$$y - 6 = 12(x - 2), \quad \text{which is also} \quad y = 12x - 18.$$

There is another important line. It is *perpendicular* to the tangent line and *perpendicular* to the curve. This is the **normal line** in Figure 2.6. Its new feature is its slope. When the tangent line has slope  $m$ , the normal line has slope  $-1/m$ . (Rule: Slopes of

**Fig. 2.6** Tangent line  $y - y_0 = m(x - x_0)$ . Normal line  $y - y_0 = -\frac{1}{m}(x - x_0)$ . Leaving a roller-coaster and catching up to a car.

perpendicular lines multiply to give  $-1$ .) Example 2 has  $m = 12$ , so the normal line has slope  $-1/12$ :

$$\text{tangent line: } y - 6 = 12(x - 2) \quad \text{normal line: } y - 6 = -\frac{1}{12}(x - 2).$$

Light rays travel in the normal direction. So do brush fires—they move perpendicular to the fire line. Use the point-slope form! The tangent is  $y = 12x - 18$ , the normal is not  $y = -\frac{1}{12}x - 18$ .

**EXAMPLE 3** You are on a roller-coaster whose track follows  $y = x^2 + 4$ . You see a friend at  $(0, 0)$  and want to get there quickly. Where do you step off?

**Solution** Your path will be the tangent line (at high speed). The problem is **to choose  $x = a$  so the tangent line passes through  $x = 0, y = 0$** . When you step off at  $x = a$ ,

the height is  $y = a^2 + 4$  and the slope is  $2a$

the equation of the tangent line is  $y - (a^2 + 4) = 2a(x - a)$

this line goes through  $(0, 0)$  if  $-(a^2 + 4) = -2a^2$  or  $a = \pm 2$ .

The same problem is solved by spacecraft controllers and baseball pitchers. Releasing a ball at the right time to hit a target 60 feet away is an amazing display of calculus. Quarterbacks with a moving target should read Chapter 4 on related rates.

Here is a better example than a roller-coaster. Stopping at a red light wastes gas. It is smarter to slow down early, and then accelerate. When a car is waiting in front of you, the timing needs calculus:

**EXAMPLE 4** How much must you slow down when a red light is 72 meters away? In 4 seconds it will be green. The waiting car will accelerate at 3 meters/sec<sup>2</sup>. You cannot pass the car.

**Strategy** Slow down immediately to the speed  $V$  at which you will just catch that car. (If you wait and brake later, your speed will have to go below  $V$ .) At the catch-up time  $T$ , the cars have the same speed and same distance. **Two conditions**, so the distance functions in Figure 2.6d are tangent.

**Solution** At time  $T$ , the other car's speed is  $3(T - 4)$ . That shows the delay of 4 seconds. Speeds are equal when  $3(T - 4) = V$  or  $T = \frac{1}{3}V + 4$ . Now require equal distances. Your distance is  $V$  times  $T$ . The other car's distance is  $72 + \frac{1}{2}at^2$ :

$$72 + \frac{1}{2} \cdot 3(T - 4)^2 = VT \quad \text{becomes} \quad 72 + \frac{1}{2} \cdot \frac{1}{3}V^2 = V(\frac{1}{3}V + 4).$$

The solution is  $V = 12$  meters/second. This is 43 km/hr or 27 miles per hour.

Without the other car, you only slow down to  $V = 72/4 = 18$  meters/second. As the light turns green, you go through at 65 km/hr or 40 miles per hour. Try it.

### THE SECANT LINE CONNECTING TWO POINTS ON A CURVE

Instead of the tangent line through one point, consider the **secant line through two points**. For the tangent line the points came together. Now spread them apart. The point-slope form of a linear equation is replaced by the **two-point form**.

The equation of the curve is still  $y = f(x)$ . The first point remains at  $x = a, y = f(a)$ . The other point is at  $x = c, y = f(c)$ . The secant line goes between them, and we want its equation. This time we don't start with the slope—but  $m$  is easy to find.

### 2.3 The Slope and the Tangent Line

**EXAMPLE 5** The curve  $y = x^3 - 2$  goes through  $x = 2$ ,  $y = 6$ . It also goes through  $x = 3$ ,  $y = 25$ . The slope between those points is

$$m = \frac{\text{change in } y}{\text{change in } x} = \frac{25 - 6}{3 - 2} = 19.$$

The point-slope form (at the first point) is  $y - 6 = 19(x - 2)$ . This line automatically goes through the second point (3, 25). Check: 25 - 6 equals 19(3 - 2). The secant has the right slope 19 to reach the second point. It is the *average slope*  $\Delta y/\Delta x$ .

**A look ahead** The second point is going to approach the first point. The secant slope  $\Delta y/\Delta x$  will approach the tangent slope  $dy/dx$ . We discover the derivative (in the limit). That is the main point now—but not forever.

Soon you will be fast at derivatives. The exact  $dy/dx$  will be much easier than  $\Delta y/\Delta x$ . The situation is turned around as soon as you know that  $x^9$  has slope  $9x^8$ . Near  $x = 1$ , the distance *up* is about 9 times the distance *across*. To find  $\Delta y = 1.001^9 - 1^9$ , just multiply  $\Delta x = .001$  by 9. The quick approximation is .009, the calculator gives  $\Delta y = .009036$ . It is easier to follow the tangent line than the curve.

Come back to the secant line, and change numbers to letters. What line connects  $x = a$ ,  $y = f(a)$  to  $x = c$ ,  $y = f(c)$ ? A mathematician puts formulas ahead of numbers, and reasoning ahead of formulas, and ideas ahead of reasoning:

- (1) The slope is  $m = \frac{\text{distance up}}{\text{distance across}} = \frac{f(c) - f(a)}{c - a}$
- (2) The height is  $y = f(a)$  at  $x = a$
- (3) The height is  $y = f(c)$  at  $x = c$  (automatic with correct slope).

**2F** The *two-point form* uses the slope between the points:

$$\text{secant line: } y - f(a) = \left( \frac{f(c) - f(a)}{c - a} \right) (x - a). \quad (3)$$

At  $x = a$  the right side is zero. So  $y = f(a)$  on the left side. At  $x = c$  the right side has two factors  $c - a$ . They cancel to leave  $y = f(c)$ . With equation (2) for the tangent line and equation (3) for the secant line, we are ready for the moment of truth.

#### THE SECANT LINE APPROACHES THE TANGENT LINE

What comes now is pretty basic. It matches what we did with velocities:

$$\text{average velocity} = \frac{\Delta \text{ distance}}{\Delta \text{ time}} = \frac{f(t + \Delta t) - f(t)}{\Delta t}.$$

The limit is  $df/dt$ . We now do exactly the same thing with slopes. ***The secant line turns into the tangent line as  $c$  approaches  $a$ :***

$$\text{slope of secant line: } \frac{\Delta f}{\Delta x} = \frac{f(c) - f(a)}{c - a}$$

$$\text{slope of tangent line: } \frac{df}{dx} = \text{limit of } \frac{\Delta f}{\Delta x}.$$

There stands the fundamental idea of differential calculus! You have to imagine more secant lines than I can draw in Figure 2.7, as  $c$  comes close to  $a$ . Everybody recognizes  $c - a$  as  $\Delta x$ . Do you recognize  $f(c) - f(a)$  as  $f(x + \Delta x) - f(x)$ ? It is  $\Delta f$ , the change in height. All lines go through  $x = a$ ,  $y = f(a)$ . **Their limit is the tangent line.**

**Fig. 2.7** Secants approach tangent as their slopes  $\Delta f/\Delta x$  approach  $df/dx$ .

Intuitively, the limit is pretty clear. The two points come together, and the tangent line touches the curve at *one* point. (It could touch again at faraway points.) Mathematically this limit can be tricky—it takes us from algebra to calculus. Algebra stays away from 0/0, but calculus gets as close as it can.

The new limit for  $df/dx$  looks different, but it is the same as before:

$$f'(a) = \lim_{c \rightarrow a} \frac{f(c) - f(a)}{c - a}. \quad (4)$$

**EXAMPLE 6** Find the secant lines and tangent line for  $y = f(x) = \sin x$  at  $x = 0$ .

The starting point is  $x = 0$ ,  $y = \sin 0$ . This is the origin  $(0, 0)$ . The ratio of distance up to distance across is  $(\sin c)/c$ :

$$\text{secant equation } y = \frac{\sin c}{c} x \quad \text{tangent equation } y = 1x.$$

As  $c$  approaches zero, the secant line becomes the tangent line. The limit of  $(\sin c)/c$  is not 0/0, which is meaningless, but 1, which is  $dy/dx$ .

**EXAMPLE 7** The gold you own will be worth  $\sqrt{t}$  million dollars in  $t$  years. When does the rate of increase drop to 10% of the current value, so you should sell the gold and buy a bond? At  $t = 25$ , how far does that put you ahead of  $\sqrt{t} = 5$ ?

**Solution** The rate of increase is the derivative of  $\sqrt{t}$ , which is  $1/2\sqrt{t}$ . That is 10% of the current value  $\sqrt{t}$  when  $1/2\sqrt{t} = \sqrt{t}/10$ . Therefore  $2t = 10$  or  $t = 5$ . At that time you sell the gold, leave the curve, and go onto the tangent line:

$$y - \sqrt{5} = \frac{\sqrt{5}}{10}(t - 5) \text{ becomes } y - \sqrt{5} = 2\sqrt{5} \text{ at } t = 25.$$

With straight interest on the bond, not compounded, you have reached  $y = 3\sqrt{5} = 6.7$  million dollars. The gold is worth a measly five million.

### 2.3 EXERCISES

#### Read-through questions

A straight line is determined by a points, or one point and the b. The slope of the tangent line equals the slope

of the c. The point-slope form of the tangent equation is  $y - f(a) = \underline{d}$ .

The tangent line to  $y = x^3 + x$  at  $x = 1$  has slope e. Its

equation is f. It crosses the  $y$  axis at g and the  $x$  axis at h. The normal line at this point  $(1, 2)$  has slope l. Its equation is  $y - 2 = \frac{j}{l}$ . The secant line from  $(1, 2)$  to  $(2, \underline{k})$  has slope l. Its equation is  $y - 2 = \underline{m}$ .

The point  $(c, f(c))$  is on the line  $y - f(a) = m(x - a)$  provided  $m = \underline{n}$ . As  $c$  approaches  $a$ , the slope  $m$  approaches o. The secant line approaches the p line.

- 1 (a) Find the slope of  $y = 12/x$ .  
 (b) Find the equation of the tangent line at  $(2, 6)$ .  
 (c) Find the equation of the normal line at  $(2, 6)$ .  
 (d) Find the equation of the secant line to  $(4, 3)$ .
- 2 For  $y = x^2 + x$  find equations for  
 (a) the tangent line and normal line at  $(1, 2)$ ;  
 (b) the secant line to  $x = 1 + h$ ,  $y = (1 + h)^2 + (1 + h)$ .
- 3 A line goes through  $(1, -1)$  and  $(4, 8)$ . Write its equation in point-slope form. Then write it as  $y = mx + b$ .
- 4 The tangent line to  $y = x^3 + 6x$  at the origin is  $y = \underline{\hspace{2cm}}$ . Does it cross the curve again?
- 5 The tangent line to  $y = x^3 - 3x^2 + x$  at the origin is  $y = \underline{\hspace{2cm}}$ . It is also the secant line to the point       .
- 6 Find the tangent line to  $x = y^2$  at  $x = 4, y = 2$ .
- 7 For  $y = x^2$  the secant line from  $(a, a^2)$  to  $(c, c^2)$  has the equation       . Do the division by  $c - a$  to find the tangent line as  $c$  approaches  $a$ .
- 8 Construct a function that has the same slope at  $x = 1$  and  $x = 2$ . Then find two points where  $y = x^4 - 2x^2$  has the same tangent line (draw the graph).
- 9 Find a curve that is tangent to  $y = 2x - 3$  at  $x = 5$ . Find the normal line to that curve at  $(5, 7)$ .
- 10 For  $y = 1/x$  the secant line from  $(a, 1/a)$  to  $(c, 1/c)$  has the equation       . Simplify its slope and find the limit as  $c$  approaches  $a$ .
- 11 What are the equations of the tangent line and normal line to  $y = \sin x$  at  $x = \pi/2$ ?
- 12 If  $c$  and  $a$  both approach an in-between value  $x = b$ , then the secant slope  $(f(c) - f(a))/(c - a)$  approaches       .
- 13 At  $x = a$  on the graph of  $y = 1/x$ , compute  
 (a) the equation of the tangent line  
 (b) the points where that line crosses the axes.  
 The triangle between the tangent line and the axes always has area       .
- 14 Suppose  $g(x) = f(x) + 7$ . The tangent lines to  $f$  and  $g$  at  $x = 4$  are       . True or false: The distance between those lines is 7.

15 Choose  $c$  so that  $y = 4x$  is tangent to  $y = x^2 + c$ . Match heights as well as slopes.

16 Choose  $c$  so that  $y = 5x - 7$  is tangent to  $y = x^2 + cx$ .

17 For  $y = x^3 + 4x^2 - 3x + 1$ , find all points where the tangent is horizontal.

18  $y = 4x$  can't be tangent to  $y = cx^2$ . Try to match heights and slopes, or draw the curves.

19 Determine  $c$  so that the straight line joining  $(0, 3)$  and  $(5, -2)$  is tangent to the curve  $y = c/(x + 1)$ .

20 Choose  $b, c, d$  so that the two parabolas  $y = x^2 + bx + c$  and  $y = dx - x^2$  are tangent to each other at  $x = 1, y = 0$ .

21 The graph of  $f(x) = x^3$  goes through  $(1, 1)$ .

- (a) Another point is  $x = c = 1 + h, y = f(c) = \underline{\hspace{2cm}}$ .
- (b) The change in  $f$  is  $\Delta f = \underline{\hspace{2cm}}$ .
- (c) The slope of the secant is  $m = \underline{\hspace{2cm}}$ .
- (d) As  $h$  goes to zero,  $m$  approaches       .

22 Construct a function  $y = f(x)$  whose tangent line at  $x = 1$  is the same as the secant that meets the curve again at  $x = 3$ .

23 Draw two curves bending away from each other. Mark the points  $P$  and  $Q$  where the curves are closest. At those points, the tangent lines are        and the normal lines are       .

\*24 If the parabolas  $y = x^2 + 1$  and  $y = x - x^2$  come closest at  $(a, a^2 + 1)$  and  $(c, c - c^2)$ , set up two equations for  $a$  and  $c$ .

25 A light ray comes down the line  $x = a$ . It hits the parabolic reflector  $y = x^2$  at  $P = (a, a^2)$ .

- (a) Find the tangent line at  $P$ . Locate the point  $Q$  where that line crosses the  $y$  axis.
- (b) Check that  $P$  and  $Q$  are the same distance from the focus at  $F = (0, \frac{1}{4})$ .
- (c) Show from (b) that the figure has equal angles.
- (d) What law of physics makes every ray reflect off the parabola to the focus at  $F$ ?

26 In a bad reflector  $y = 2/x$ , a ray down one special line  $x = a$  is reflected horizontally. What is  $a$ ?

- 27** For the parabola  $4py = x^2$ , where is the slope equal to 1? At that point a vertical ray will reflect horizontally. So the focus is at  $(0, \underline{\hspace{2cm}})$ .
- 28** Why are these statements wrong? Make them right.
- If  $y = 2x$  is the tangent line at  $(1, 2)$  then  $y = -\frac{1}{2}x$  is the normal line.
  - As  $c$  approaches  $a$ , the secant slope  $(f(c) - f(a))/(c - a)$  approaches  $(f(a) - f(a))/(a - a)$ .
  - The line through  $(2, 3)$  with slope 4 is  $y - 2 = 4(x - 3)$ .
- 29** A ball goes around a circle:  $x = \cos t$ ,  $y = \sin t$ . At  $t = 3\pi/4$  the ball flies off on the tangent line. Find the equation of that line and the point where the ball hits the ground ( $y = 0$ ).
- 30** If the tangent line to  $y = f(x)$  at  $x = a$  is the same as the tangent line to  $y = g(x)$  at  $x = b$ , find two equations that must be satisfied by  $a$  and  $b$ .
- 31** Draw a circle of radius 1 resting in the parabola  $y = x^2$ . At the touching point  $(a, a^2)$ , the equation of the normal line is  $\underline{\hspace{2cm}}$ . That line has  $x = 0$  when  $y = \underline{\hspace{2cm}}$ . The distance to  $(a, a^2)$  equals the radius 1 when  $a = \underline{\hspace{2cm}}$ . This locates the touching point.
- 32** Follow Problem 31 for the flatter parabola  $y = \frac{1}{2}x^2$  and explain where the circle rests.
- 33** You are applying for a \$1000 scholarship and your time is worth \$10 a hour. If the chance of success is  $1 - (1/x)$  from  $x$  hours of writing, when should you stop?
- 34** Suppose  $|f(c) - f(a)| \leq |c - a|$  for every pair of points  $a$  and  $c$ . Prove that  $|df/dx| \leq 1$ .
- 35** From which point  $x = a$  does the tangent line to  $y = 1/x^2$  hit the  $x$  axis at  $x = 3$ ?
- 36** If  $u(x)/v(x) = 7$  find  $u'(x)/v'(x)$ . Also find  $(u(x)/v(x))'$ .
- 37** Find  $f(c) = 1.001^{10}$  in two ways—by calculator and by  $f(c) - f(a) \approx f'(a)(c - a)$ . Choose  $a = 1$  and  $f(x) = x^{10}$ .
- 38** At a distance  $\Delta x$  from  $x = 1$ , how far is the curve  $y = 1/x$  above its tangent line?
- 39** At a distance  $\Delta x$  from  $x = 2$ , how far is the curve  $y = x^3$  above its tangent line?
- 40** Based on Problem 38 or 39, the distance between curve and tangent line grows like what power  $(\Delta x)^p$ ?
- 41** The tangent line to  $f(x) = x^2 - 1$  at  $x_0 = 2$  crosses the  $x$  axis at  $x_1 = \underline{\hspace{2cm}}$ . The tangent line at  $x_1$  crosses the  $x$  axis at  $x_2 = \underline{\hspace{2cm}}$ . Draw the curve and the two lines, which are the beginning of *Newton's method* to solve  $f(x) = 0$ .
- 42** (Puzzle) The equation  $y = mx + b$  requires *two* numbers, the point-slope form  $y - f(a) = f'(a)(x - a)$  requires *three*, and the two-point form requires *four*:  $a, f(a), c, f(c)$ . How can this be?
- 43** Find the time  $T$  at the tangent point in Example 4, when you catch the car in front.
- 44** If the waiting car only accelerates at 2 meters/sec<sup>2</sup>, what speed  $V$  must you slow down to?
- 45** A thief 40 meters away runs toward you at 8 meters per second. What is the smallest acceleration so that  $v = at$  keeps you in front?
- 46** With 8 meters to go in a relay race, you slow down badly ( $f = -8 + 6t - \frac{1}{2}t^2$ ). How fast should the next runner start (choose  $v$  in  $f = vt$ ) so you can just pass the baton?

## 2.4 The Derivative of the Sine and Cosine

This section does two things. One is to compute the derivatives of  $\sin x$  and  $\cos x$ . The other is to explain why these functions are so important. They describe *oscillation*, which will be expressed in words and equations. You will see a “*differential equation*.” It involves the derivative of an unknown function  $y(x)$ .

The differential equation will say that the *second* derivative—*the derivative of the derivative*—is equal and opposite to  $y$ . In symbols this is  $y'' = -y$ . Distance in one direction leads to acceleration in the other direction. That makes  $y$  and  $y'$  and  $y''$  all oscillate. The solutions to  $y'' = -y$  are  $\sin x$  and  $\cos x$  and all their combinations.

We begin with the slope. The derivative of  $y = \sin x$  is  $y' = \cos x$ . There is no reason for that to be a mystery, but I still find it beautiful. Chapter 1 followed a ball around a circle; the shadow went up and down. Its height was  $\sin t$  and its velocity was  $\cos t$ .

## 2.4 The Derivative of the Sine and Cosine

We now find that derivative by *the standard method of limits*, when  $y(x) = \sin x$ :

$$\frac{dy}{dx} = \text{limit of } \frac{\Delta y}{\Delta x} = \lim_{h \rightarrow 0} \frac{\sin(x+h) - \sin x}{h}. \quad (1)$$

The sine is harder to work with than  $x^2$  or  $x^3$ . Where we had  $(x+h)^2$  or  $(x+h)^3$ , we now have  $\sin(x+h)$ . This calls for one of the basic “addition formulas” from trigonometry, reviewed in Section 1.5:

$$\sin(x+h) = \sin x \cos h + \cos x \sin h \quad (2)$$

$$\cos(x+h) = \cos x \cos h - \sin x \sin h. \quad (3)$$

Equation (2) puts  $\Delta y = \sin(x+h) - \sin x$  in a new form:

$$\frac{\Delta y}{\Delta x} = \frac{\sin x \cos h + \cos x \sin h - \sin x}{h} = \sin x \left( \frac{\cos h - 1}{h} \right) + \cos x \left( \frac{\sin h}{h} \right). \quad (4)$$

The ratio splits into two simpler pieces on the right. Algebra and trigonometry got us this far, and now comes the calculus problem. *What happens as  $h \rightarrow 0$ ?* It is no longer easy to divide by  $h$ . (I will not even mention the unspeakable crime of writing  $(\sin h)/h = \sin$ .) There are two critically important limits—the first is zero and the second is one:

$$\lim_{h \rightarrow 0} \frac{\cos h - 1}{h} = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} \frac{\sin h}{h} = 1. \quad (5)$$

The careful reader will object that limits have not been defined! You may further object to computing these limits separately, before combining them into equation (4). Nevertheless—following the principle of *ideas now, rigor later*—I would like to proceed. It is entirely true that the limit of (4) comes from the two limits in (5):

$$\frac{dy}{dx} = (\sin x)(\text{first limit}) + (\cos x)(\text{second limit}) = 0 + \cos x. \quad (6)$$

The secant slope  $\Delta y/\Delta x$  has approached the tangent slope  $dy/dx$ .

**2G** The derivative of  $y = \sin x$  is  $dy/dx = \cos x$ .

We cannot pass over the crucial step—the two limits in (5). They contain the real ideas. *Both ratios become 0/0 if we just substitute  $h = 0$* . Remember that the cosine of a zero angle is 1, and the sine of a zero angle is 0. Figure 2.8a shows a small angle  $h$  (as near to zero as we could reasonably draw). The edge of length  $\sin h$  is close to zero, and the edge of length  $\cos h$  is near 1. Figure 2.8b shows how the ratio of  $\sin h$  to  $h$  (both headed for zero) gives the slope of the sine curve at the start.

When two functions approach zero, their ratio might do anything. We might have

$$\frac{h^2}{h} \rightarrow 0 \quad \text{or} \quad \frac{h}{h} \rightarrow 1 \quad \text{or} \quad \frac{\sqrt{h}}{h} \rightarrow \infty.$$

No clue comes from 0/0. What matters is *whether the top or bottom goes to zero more quickly*. Roughly speaking, we want to show that  $(\cos h - 1)/h$  is like  $h^2/h$  and  $(\sin h)/h$  is like  $h/h$ .

**Time out** The graph of  $\sin x$  is in Figure 2.9 (in black). The graph of  $\sin(x + \Delta x)$  sits just beside it (in red). The height difference is  $\Delta f$  when the shift distance is  $\Delta x$ .

Fig. 2.8

**Fig. 2.9**  $\sin(x+h)$  with  $h = 10^\circ = \pi/18$  radians.  $\Delta f/\Delta x$  is close to  $\cos x$ .

Now divide by that small number  $\Delta x$  (or  $h$ ). The second figure shows  $\Delta f/\Delta x$ . It is close to  $\cos x$ . (Look how it starts—it is not quite  $\cos x$ .) Mathematics will prove that the limit is  $\cos x$  exactly, when  $\Delta x \rightarrow 0$ . Curiously, the reasoning concentrates on only one point ( $x = 0$ ). The slope at that point is  $\cos 0 = 1$ .

We now prove this:  $\sin \Delta x$  divided by  $\Delta x$  goes to 1. The sine curve starts with slope 1. By the addition formula for  $\sin(x+h)$ , this answer at one point will lead to the slope  $\cos x$  at all points.

**Question** Why does the graph of  $f(x+\Delta x)$  shift *left* from  $f(x)$  when  $\Delta x > 0$ ?

**Answer** When  $x = 0$ , the shifted graph is already showing  $f(\Delta x)$ . In Figure 2.9a, the red graph is shifted *left* from the black graph. The red graph shows  $\sin h$  when the black graph shows  $\sin 0$ .

#### THE LIMIT OF $(\sin h)/h$ IS 1

There are several ways to find this limit. The direct approach is to let a computer draw a graph. Figure 2.10a is very convincing. **The function  $(\sin h)/h$  approaches 1 at the key point  $h = 0$ .** So does  $(\tan h)/h$ . In practice, the only danger is that you might get a message like “undefined function” and no graph. (The machine may refuse to divide by zero at  $h = 0$ . Probably you can get around that.) Because of the importance of this limit, I want to give a mathematical proof that it equals 1.

**Fig. 2.10**  $(\sin h)/h$  squeezed between  $\cos x$  and 1;  $(\tan h)/h$  decreases to 1.

Figure 2.10b indicates, but still only graphically, that  $\sin h$  stays *below*  $h$ . (The first graph shows that too;  $(\sin h)/h$  is below 1.) We also see that  $\tan h$  stays *above*  $h$ . Remember that the tangent is the ratio of sine to cosine. Dividing by the cosine is enough to push the tangent above  $h$ . The crucial inequalities (to be proved when  $h$  is small and positive) are

$$\sin h < h \quad \text{and} \quad \tan h > h. \quad (7)$$

Since  $\tan h = (\sin h)/(\cos h)$ , those are the same as

$$\frac{\sin h}{h} < 1 \quad \text{and} \quad \frac{\sin h}{h} > \cos h. \quad (8)$$

What happens as  $h$  goes to zero? *The ratio  $(\sin h)/h$  is squeezed between  $\cos h$  and 1.* But  $\cos h$  is approaching 1! The squeeze as  $h \rightarrow 0$  leaves only one possibility for  $(\sin h)/h$ , which is caught in between: *The ratio  $(\sin h)/h$  approaches 1.*

Figure 2.10 shows that “squeeze play.” *If two functions approach the same limit, so does any function caught in between.* This is proved at the end of Section 2.6.

For negative values of  $h$ , which are absolutely allowed, the result is the same. To the left of zero,  $h$  reverses sign and  $\sin h$  reverses sign. The ratio  $(\sin h)/h$  is unchanged. (The sine is an odd function:  $\sin(-h) = -\sin h$ .) The ratio is an even function, symmetric around zero and approaching 1 from both sides.

The proof depends on  $\sin h < h < \tan h$ , which is displayed by the graph but not explained. We go back to right triangles.

**Fig. 2.11** Line shorter than arc:  $2 \sin h < 2h$ . Areas give  $h < \tan h$ .

Figure 2.11a shows why  $\sin h < h$ . The straight line  $PQ$  has length  $2 \sin h$ . The circular arc must be longer, because the shortest distance between two points is a straight line.<sup>†</sup> The arc  $PQ$  has length  $2h$ . (Important: *When the radius is 1, the arc length equals the angle.* The full circumference is  $2\pi$  and the full angle is also  $2\pi$ .) *The straight distance  $2 \sin h$  is less than the circular distance  $2h$ , so  $\sin h < h$ .*

Figure 2.11b shows why  $h < \tan h$ . This time we look at *areas*. The triangular area is  $\frac{1}{2}(\text{base})(\text{height}) = \frac{1}{2}(1)(\tan h)$ . Inside that triangle is the shaded sector of the circle. Its area is  $h/2\pi$  times the area of the whole circle (because the angle is that fraction of the whole angle). The circle has area  $\pi r^2 = \pi$ , so multiplication by  $h/2\pi$  gives  $\frac{1}{2}h$  for the area of the sector. Comparing with the triangle around it,  $\frac{1}{2}\tan h > \frac{1}{2}h$ .

The inequalities  $\sin h < h < \tan h$  are now proved. The squeeze in equation (8) produces  $(\sin h)/h \rightarrow 1$ . Q.E.D. Problem 13 shows how to prove  $\sin h < h$  from areas.

**Note** All angles  $x$  and  $h$  are being measured in radians. *In degrees,  $\cos x$  is not the derivative of  $\sin x$ .* A degree is much less than a radian, and  $dy/dx$  is reduced by the factor  $2\pi/360$ .

#### THE LIMIT OF $(\cos h - 1)/h$ IS 0

This second limit is different. We will show that  $1 - \cos h$  shrinks to zero *more quickly* than  $h$ . Cosines are connected to sines by  $(\sin h)^2 + (\cos h)^2 = 1$ . We start from the

<sup>†</sup>If we try to prove that, we will be here all night. Accept it as true.

known fact  $\sin h < h$  and work it into a form involving cosines:

$$(1 - \cos h)(1 + \cos h) = 1 - (\cos h)^2 = (\sin h)^2 < h^2. \quad (9)$$

Note that everything is positive. Divide through by  $h$  and also by  $1 + \cos h$ :

$$0 < \frac{1 - \cos h}{h} < \frac{h}{1 + \cos h}. \quad (10)$$

Our ratio is caught in the middle. *The right side goes to zero because  $h \rightarrow 0$ .* This is another “squeeze”—there is no escape. Our ratio goes to zero.

For  $\cos h - 1$  or for negative  $h$ , the signs change but minus zero is still zero. This confirms equation (6). The slope of  $\sin x$  is  $\cos x$ .

**Remark** Equation (10) also shows that  $1 - \cos h$  is approximately  $\frac{1}{2}h^2$ . The 2 comes from  $1 + \cos h$ . This is a basic purpose of calculus—to find simple approximations like  $\frac{1}{2}h^2$ . A “tangent parabola”  $1 - \frac{1}{2}h^2$  is close to the top of the cosine curve.

### THE DERIVATIVE OF THE COSINE

This will be easy. The quick way to differentiate  $\cos x$  is to shift the sine curve by  $\pi/2$ . That yields the cosine curve (solid line in Figure 2.12b). The derivative also shifts by  $\pi/2$  (dotted line). *The derivative of  $\cos x$  is  $-\sin x$ .*

Notice how the dotted line (the slope) goes below zero when the solid line turns downward. The slope equals zero when the solid line is level. **Increasing functions have positive slopes. Decreasing functions have negative slopes.** That is important, and we return to it.

There is more information in  $dy/dx$  than “function rising” or “function falling.” The slope tells *how quickly* the function goes up or down. It gives the *rate of change*. The slope of  $y = \cos x$  can be computed in the normal way, as the limit of  $\Delta y/\Delta x$ :

$$\begin{aligned}\frac{\Delta y}{\Delta x} &= \frac{\cos(x+h) - \cos x}{h} = \cos x \left( \frac{\cos h - 1}{h} \right) - \sin x \left( \frac{\sin h}{h} \right) \\ \frac{dy}{dx} &= (\cos x)(0) - (\sin x)(1) = -\sin x.\end{aligned}\quad (11)$$

The first line came from formula (3) for  $\cos(x+h)$ . The second line took limits, reaching 0 and 1 as before. This confirms the graphical proof that the slope of  $\cos x$  is  $-\sin x$ .

**Fig. 2.12**  $y(x)$  increases where  $y'$  is positive.  $y(x)$  bends up where  $y''$  is positive.

### THE SECOND DERIVATIVES OF THE SINE AND COSINE

We now introduce *the derivative of the derivative*. That is the *second derivative* of the original function. It tells how fast the slope is changing, not how fast  $y$  itself is

changing. The second derivative is the “rate of change of the velocity.” A straight line has constant slope (constant velocity), so its second derivative is zero:

$$f(t) = 5t \text{ has } df/dt = 5 \text{ and } d^2f/dt^2 = 0.$$

The parabola  $y = x^2$  has slope  $2x$  (linear) which has slope 2 (constant). Similarly

$$f(t) = \frac{1}{2}at^2 \text{ has } df/dt = at \text{ and } d^2f/dt^2 = a.$$

There stands the notation  $d^2f/dt^2$  (or  $d^2y/dx^2$ ) for the second derivative. A short form is  $f''$  or  $y''$ . (This is pronounced *f double prime* or *y double prime*). Example: The second derivative of  $y = x^3$  is  $y'' = 6x$ .

In the distance-velocity problem,  $f''$  is *acceleration*. It tells how fast  $v$  is changing, while  $v$  tells how fast  $f$  is changing. Where  $df/dt$  was distance/time, the second derivative is distance/(time)<sup>2</sup>. The acceleration due to gravity is about 32 ft/sec<sup>2</sup> or 9.8 m/sec<sup>2</sup>, which means that  $v$  increases by 32 ft/sec in one second. It does not mean that the distance increases by 32 feet!

The graph of  $y = \sin t$  increases at the start. Its derivative  $\cos t$  is positive. However the second derivative is  $-\sin t$ . ***The curve is bending down while going up.*** The arch is “***concave down***” because  $y'' = -\sin t$  is negative.

At  $t = \pi$  the curve reaches zero and goes negative. The second derivative becomes positive. ***Now the curve bends upward.*** The lower arch is “***concave up***.”

$y'' > 0$  means that  $y'$  increases so  $y$  bends upward (concave up)

$y'' < 0$  means that  $y'$  decreases so  $y$  bends down (concave down).

Chapter 3 studies these things properly—here we get an advance look for  $\sin t$ .

The remarkable fact about the sine and cosine is that  $y'' = -y$ . That is unusual and special: *acceleration = -distance*. The greater the distance, the greater the force pulling back:

$$y = \sin t \text{ has } dy/dt = +\cos t \text{ and } d^2y/dt^2 = -\sin t = -y.$$

$$y = \cos t \text{ has } dy/dt = -\sin t \text{ and } d^2y/dt^2 = -\cos t = -y.$$

**Question** Does  $d^2y/dt^2 < 0$  mean that the distance  $y(t)$  is decreasing?

**Answer** No. Absolutely not! It means that  $dy/dt$  is decreasing, not necessarily  $y$ . At the start of the sine curve,  $y$  is still increasing but  $y'' < 0$ .

Sines and cosines give *simple harmonic motion*—up and down, forward and back, out and in, tension and compression. Stretch a spring, and the restoring force pulls it back. Push a swing up, and gravity brings it down. These motions are controlled by a ***differential equation***:

$$\frac{d^2y}{dt^2} = -y. \tag{12}$$

All solutions are combinations of the sine and cosine:  $y = A \sin t + B \cos t$ .

This is not a course on differential equations. But you have to see the purpose of calculus. It models events by equations. It models oscillation by equation (12). Your heart fills and empties. Balls bounce. Current alternates. The economy goes up and down:

high prices → high production → low prices → ...

We can't live without oscillations (or differential equations).

## 2.4 EXERCISES

## Read-through questions

The derivative of  $y = \sin x$  is  $y' = \underline{\text{a}}$ . The second derivative (the b of the derivative) is  $y'' = \underline{\text{c}}$ . The fourth derivative is  $y''' = \underline{\text{d}}$ . Thus  $y = \sin x$  satisfies the differential equations  $y'' = \underline{\text{e}}$  and  $y''' = \underline{\text{f}}$ . So does  $y = \cos x$ , whose second derivative is g.

All these derivatives come from one basic limit:  $(\sin h)/h$  approaches h. The sine of .01 radians is very close to l. So is the j of .01. The cosine of .01 is not .99, because  $1 - \cos h$  is much k than  $h$ . The ratio  $(1 - \cos h)/h^2$  approaches l. Therefore  $\cos h$  is close to  $1 - \frac{1}{2}h^2$  and  $\cos .01 \approx \underline{m}$ . We can replace  $h$  by  $x$ .

The differential equation  $y'' = -y$  leads to n. When  $y$  is positive,  $y'$  is o. Therefore  $y'$  is p. Eventually  $y$  goes below zero and  $y''$  becomes q. Then  $y'$  is r. Examples of oscillation in real life are s and t.

1 Which of these ratios approach 1 as  $h \rightarrow 0$ ?

- (a)  $\frac{h}{\sin h}$     (b)  $\frac{\sin^2 h}{h^2}$     (c)  $\frac{\sin h}{\sin 2h}$     (d)  $\frac{\sin(-h)}{h}$

2 (Calculator) Find  $(\sin h)/h$  at  $h = 0.5$  and  $0.1$  and  $.01$ . Where does  $(\sin h)/h$  go above .99?

3 Find the limits as  $h \rightarrow 0$  of

- (a)  $\frac{\sin^2 h}{h}$     (b)  $\frac{\sin 5h}{5h}$     (c)  $\frac{\sin 5h}{h}$     (d)  $\frac{\sin h}{5h}$

4 Where does  $\tan h = 1.01h$ ? Where does  $\tan h = h$ ?

5  $y = \sin x$  has period  $2\pi$ , which means that  $\sin x = \underline{\text{_____}}$ . The limit of  $(\sin(2\pi + h) - \sin 2\pi)/h$  is 1 because \_\_\_\_\_. This gives  $dy/dx$  at  $x = \underline{\text{_____}}$ .

6 Draw  $\cos(x + \Delta x)$  next to  $\cos x$ . Mark the height difference  $\Delta y$ . Then draw  $\Delta y/\Delta x$  as in Figure 2.9.

7 The key to trigonometry is  $\cos^2 \theta = 1 - \sin^2 \theta$ . Set  $\sin \theta \approx \theta$  to find  $\cos^2 \theta \approx 1 - \theta^2$ . The square root is  $\cos \theta \approx 1 - \frac{1}{2}\theta^2$ . Reason: Squaring gives  $\cos^2 \theta \approx \underline{\text{_____}}$  and the correction term \_\_\_\_\_ is very small near  $\theta = 0$ .

8 (Calculator) Compare  $\cos \theta$  with  $1 - \frac{1}{2}\theta^2$  for

- (a)  $\theta = 0.1$     (b)  $\theta = 0.5$     (c)  $\theta = 30^\circ$     (d)  $\theta = 3^\circ$ .

9 Trigonometry gives  $\cos \theta = 1 - 2 \sin^2 \frac{1}{2}\theta$ . The approximation  $\sin \frac{1}{2}\theta \approx \underline{\text{_____}}$  leads directly to  $\cos \theta \approx 1 - \frac{1}{2}\theta^2$ .

10 Find the limits as  $h \rightarrow 0$ :

- (a)  $\frac{1 - \cos h}{h^2}$     (b)  $\frac{1 - \cos^2 h}{h^2}$   
 (c)  $\frac{1 - \cos^2 h}{\sin^2 h}$     (d)  $\frac{1 - \cos 2h}{h}$

11 Find by calculator or calculus:

$$(a) \lim_{h \rightarrow 0} \frac{\sin 3h}{\sin 2h} \quad (b) \lim_{h \rightarrow 0} \frac{1 - \cos 2h}{1 - \cos h}.$$

12 Compute the slope at  $x = 0$  directly from limits:

$$(a) y = \tan x \quad (b) y = \sin(-x)$$

13 The unmarked points in Figure 2.11 are  $P$  and  $S$ . Find the height  $PS$  and the area of triangle  $OPR$ . Prove by areas that  $\sin h < h$ .

14 The slopes of  $\cos x$  and  $1 - \frac{1}{2}x^2$  are  $-\sin x$  and \_\_\_\_\_. The slopes of  $\sin x$  and \_\_\_\_\_ are  $\cos x$  and  $1 - \frac{1}{2}x^2$ .

15 Chapter 10 gives an infinite series for  $\sin x$ :

$$\sin x = \frac{x}{1} - \frac{x^3}{3 \cdot 2 \cdot 1} + \frac{x^5}{5 \cdot 4 \cdot 3 \cdot 2 \cdot 1} - \dots$$

From the derivative find the series for  $\cos x$ . Then take its derivative to get back to  $-\sin x$ .

16 A centered difference for  $f(x) = \sin x$  is

$$\frac{f(x+h) - f(x-h)}{2h} = \frac{\sin(x+h) - \sin(x-h)}{2h} = ?$$

Use the addition formula (2). Then let  $h \rightarrow 0$ .

17 Repeat Problem 16 to find the slope of  $\cos x$ . Use formula (3) to simplify  $\cos(x+h) - \cos(x-h)$ .

18 Find the tangent line to  $y = \sin x$  at

- (a)  $x = 0$     (b)  $x = \pi$     (c)  $x = \pi/4$

19 Where does  $y = \sin x + \cos x$  have zero slope?

20 Find the derivative of  $\sin(x+1)$  in two ways:

- (a) Expand to  $\sin x \cos 1 + \cos x \sin 1$ . Compute  $dy/dx$ .  
 (b) Divide  $\Delta y = \sin(x+1+\Delta x) - \sin(x+1)$  by  $\Delta x$ . Write  $X$  instead of  $x+1$ . Let  $\Delta x$  go to zero.

21 Show that  $(\tan h)/h$  is squeezed between 1 and  $1/\cos h$ . As  $h \rightarrow 0$  the limit is \_\_\_\_\_.

22 For  $y = \sin 2x$ , the ratio  $\Delta y/h$  is

$$\frac{\sin 2(x+h) - \sin 2x}{h} = \frac{\sin 2x(\cos 2h - 1) + \cos 2x \sin 2h}{h}.$$

Explain why the limit  $dy/dx$  is  $2 \cos 2x$ .

23 Draw the graph of  $y = \sin \frac{1}{2}x$ . State its slope at  $x = 0, \pi/2, \pi$ , and  $2\pi$ . Does  $\frac{1}{2}\sin x$  have the same slopes?

24 Draw the graph of  $y = \sin x + \sqrt{3} \cos x$ . Its maximum value is  $y = \underline{\text{_____}}$  at  $x = \underline{\text{_____}}$ . The slope at that point is \_\_\_\_\_.

25 By combining  $\sin x$  and  $\cos x$ , find a combination that starts at  $x = 0$  from  $y = 2$  with slope 1. This combination also solves  $y'' = \underline{\text{_____}}$ .

**26 True or false,** with reason:

- (a) The derivative of  $\sin^2 x$  is  $\cos^2 x$
- (b) The derivative of  $\cos(-x)$  is  $\sin x$
- (c) A positive function has a negative second derivative.
- (d) If  $y'$  is increasing then  $y''$  is positive.

**27** Find solutions to  $dy/dx = \sin 3x$  and  $dy/dx = \cos 3x$ .

**28** If  $y = \sin 5x$  then  $y' = 5 \cos 5x$  and  $y'' = -25 \sin 5x$ . So this function satisfies the differential equation  $y'' = \underline{\hspace{2cm}}$ .

**29** If  $h$  is measured in degrees, find  $\lim_{h \rightarrow 0} (\sin h)/h$ . You could set your calculator in degree mode.

**30** Write down a ratio that approaches  $dy/dx$  at  $x = \pi$ . For  $y = \sin x$  and  $\Delta x = .01$  compute that ratio.

**31** By the square rule, the derivative of  $(u(x))^2$  is  $2u du/dx$ . Take the derivative of each term in  $\sin^2 x + \cos^2 x = 1$ .

**32** Give an example of oscillation that does not come from physics. Is it simple harmonic motion (one frequency only)?

**33** Explain the second derivative in your own words.

## 2.5 The Product and Quotient and Power Rules

What are the derivatives of  $x + \sin x$  and  $x \sin x$  and  $1/\sin x$  and  $x/\sin x$  and  $\sin^n x$ ? Those are made up from the familiar pieces  $x$  and  $\sin x$ , but we need new rules. Fortunately they are rules that apply to every function, so they can be established once and for all. If we know the separate derivatives of two functions  $u$  and  $v$ , then the derivatives of  $u + v$  and  $uv$  and  $1/v$  and  $u/v$  and  $u^n$  are immediately available.

This is a straightforward section, with those five rules to learn. It is also an important section, containing most of the working tools of differential calculus. But I am afraid that five rules and thirteen examples (which we need—the eyes glaze over with formulas alone) make a long list. At least the easiest rule comes first. *When we add functions, we add their derivatives.*

### Sum Rule

The derivative of the sum  $u(x) + v(x)$  is  $\frac{d}{dx}(u + v) = \frac{du}{dx} + \frac{dv}{dx}$ . (1)

**EXAMPLE 1** The derivative of  $x + \sin x$  is  $1 + \cos x$ . That is tremendously simple, but it is fundamental. The interpretation for distances may be more confusing (and more interesting) than the rule itself:

Suppose a train moves with velocity 1. The distance at time  $t$  is  $t$ . On the train a professor paces back and forth (in simple harmonic motion). His distance from his seat is  $\sin t$ . Then the total distance from his starting point is  $t + \sin t$ , and his velocity (train speed plus walking speed) is  $1 + \cos t$ .

If you add distances, you add velocities. Actually that example is ridiculous, because the professor's maximum speed equals the train speed ( $= 1$ ). He is running like mad, not pacing. Occasionally he is standing still with respect to the ground.

The sum rule is a special case of a bigger rule called “*linearity*.” It applies when we add or subtract functions and multiply them by constants—as in  $3x - 4 \sin x$ . By linearity the derivative is  $3 - 4 \cos x$ . The rule works for all functions  $u(x)$  and  $v(x)$ . A *linear combination* is  $y(x) = au(x) + bv(x)$ , where  $a$  and  $b$  are any real numbers. Then  $\Delta y/\Delta x$  is

$$\frac{au(x + \Delta x) + bv(x + \Delta x) - au(x) - bv(x)}{\Delta x} = a \frac{u(x + \Delta x) - u(x)}{\Delta x} + b \frac{v(x + \Delta x) - v(x)}{\Delta x}.$$
